Lymphoma induction and T-cell transformation by herpesvirus saimiri strain C488 depends on two viral oncoproteins, StpC and Tip. The major interaction partner of Tip is the protein tyrosine kinase Lck, a key regulator of T-cell activation. The Lck binding domain (LBD) of Tip comprises two interaction motifs, a proline-rich SH3 domain-binding sequence (SH3B) and a region with homology to the C terminus of Src family kinase domains (CSKH). In addition, biophysical binding analyses with purified Lck-SH2 domain suggest the phosphorylated tyrosine residue 127 of Tip (pY127) as a potential third Lck interaction site. Here, we addressed the relevance of the individual binding motifs, SH3B, CSKH, and pY127, for Tip-Lck interaction and for human T-cell transformation. Both motifs within the LBD displayed Lck binding activities and cooperated to achieve a highly efficient interaction, while pY127, the major tyrosine phosphorylation site of Tip, did not enhance Lck binding in T cells. Herpesvirus saimiri strain C488 recombinants lacking one or both LBD motifs of Tip lost their transforming potential on human cord blood lymphocytes. Recombinant virus expressing Tip with a mutation at position Y127 was still able to transform human T lymphocytes but, in contrast to wild-type virus, was strictly dependent on exogenous interleukin-2. Thus, the strong Lck binding mediated by cooperation of both LBD motifs was essential for the transformation of human T cells by herpesvirus saimiri C488. The major tyrosine phosphorylation site Y127 of Tip was particularly required for transformation in the absence of exogenous interleukin-2, suggesting its involvement in cytokine signaling pathways.

Herpesvirus saimiri (saimiriine herpesvirus type 2) causes fatal T-lymphoproliferative disorders in nonhuman primates and transforms T cells to permanent growth in vitro (reviewed in reference 25). Virus isolates are assigned to three subgroups, A, B, and C, according to pathogenic properties and sequence variations in a specific region of the viral genome (16, 53). A single open reading frame within this variable viral DNA segment was found to be essential for the oncogenic and in vitro-transforming phenotype of a herpesvirus saimiri subgroup A strain (57). Virus strains of subgroup C, which are in accordance with the T-cell phenotype of the tumors in transgenic mice, Tip directly binds to the Src family tyrosine kinase Lck, which is a key regulator of T-cell activation (7, 37).

The strong interaction of Tip with Lck relies on the Lck binding domain (LBD), consisting of a 9-amino-acid motif with homology to the C termini of various Src family kinase domains (CSKH), a 20-amino-acid linker, and a 9-amino-acid proline-rich consensus sequence for SH3 domain binding (SH3B) (7, 39). In addition, a phosphorytrosyl peptide corresponding to tyrosine residue Y127 of Tip-C488, but not the one corresponding to Y114, was identified as a ligand for the SH2 domain of Lck in a biophysical assay (4). As the related positions of Tip-C484 (tyrosine residues Y72 and Y85, respectively) are substrates for Lck in transiently transfected 293T cells (32), phosphorylated Y85/Y127 might indeed represent a third Tip-Lck interaction site, but binding of full-length Tip to the Lck SH2 domain remains to be demonstrated.

Tip was also found to associate with signal transducers and activators of transcription 1 and 3 (STAT1/3) in cells expressing Lck (50). The interaction depends on tyrosine residue Y72 of Tip-C484, which is embedded in a STAT SH2 binding motif (YXPQ) conserved at position Y114 of Tip-C488 (32). These findings suggest that Tip, phosphorylated at position Y72/Y114 by Lck, binds to the SH2 domains of STAT1 and STAT3.
Recruitment by Tip and subsequent phosphorylation by Lck provide an explanation for the observed activation of STAT1 and STAT3 in the presence of Tip and Lck (32, 42, 50, 51, 60). The implication of constitutively active STATs, especially STAT3, in growth regulation and onco genesis in multiple cell types (8, 10) suggested a central role for Tip-induced STAT activation in viral T-cell transformation. However, recombinant herpesvirus saimiri C488 expressing Tip with a tyrosine-to-phenylalanine substitution at position 114 was able to transform primary human T lymphocytes in the absence of STAT1 or STAT3 activation (35). Thus, the essential function of Tip in lymphocyte transformation does not rely on Lck-mediated STAT1/3 phosphorylation.

Given the central role of Lck in T-cell activation, Tip was assumed to activate T-cell proliferation by inducing the kinase and thus mimicking T-cell receptor (TCR) ligation. In accordance with this hypothesis, several studies demonstrated a strong activation of Lck in the presence of Tip, which is achieved by cooperation of the CSKH and SH3B motifs within the LBD independently of regulatory tyrosine phosphorylation of Lck (32, 33, 42, 48, 51, 67). However, overexpression of Tip-C488 downregulated stimulation-induced cellular protein tyrosine phosphorylation in Jurkat T cells and partially reversed the phenotype of fibroblasts transformed by a constitutively active mutant of Lck (40). These effects were even enhanced when tyrosine residue Y114 in Tip-C488 was replaced by serine (Tip Y114S) (29). An explanation for these seemingly contradictory observations is provided by analyses of surface receptor levels on Tip-expressing T cells. As previously described for constitutively active Lck (19), Tip and, more prominently, Tip Y114S downregulate TCR/CD3 from the surfaces of T cells (29, 58, 59). Receptor modulation is caused by Lck-dependent endocytosis and involves a lysosomal 80-kDa protein binding to the C terminus of Tip, which targets the Lck-receptor complex to enlarged endosomal vesicles for subsequent degradation (58, 59). This process results in reduced levels of Lck and, by intracellular sequestration of signaling components, may account for the Tip-mediated block in signal transduction from the TCR to Zap70 (11). Another negative regulatory mechanism was described for lymphocytes transduced with Tip-expressing lentiviral vectors; in conjunction with Lck, Tip promotes Fas-mediated apoptosis (34). Taken together, overexpression of Tip in T cells appears to induce Lck activity, which in turn triggers feedback mechanisms that restrict cellular activation.

While all effects of Tip observed so far in transfected or transduced T cells depend on Lck, Duboise and colleagues (21) reported transformation and onco genesis by herpesvirus saimiri C488 to be independent of Tip’s ability to bind to the kinase. In their study, mutation of the SH3B motif was considered sufficient to abrogate Tip-Lck interaction, an assumption questioned by subsequent reports on residual Lck binding and activation by Tip mutated either at the SH3B or at the CSKH motif (31) and on a putative third Tip-Lck interaction site constituted by phosphorylation of tyrosine residue 127 (4).

To further analyze the role of the individual Tip-Lck interaction sites in viral T-cell transformation, we first tested all Tip mutants used for the ability to bind to Lck. Then, we introduced the same mutations into the viral genome and used the recombinant viruses to infect human cord blood lymphocytes (CBL). Both LBD motifs of Tip, CSKH and SH3B, were found to be required for growth transformation of human T cells, although their individual mutation did not completely abrogate Lck binding activity. Mutation of tyrosine residue Y127 of Tip did not reduce Lck binding in the presence of an intact LBD but interfered with the capability of recombinant virus to transform T cells in the absence of exogenous interleukin-2 (IL-2). Taken together, our data demonstrate that growth transformation by herpesvirus saimiri depends on a complex interaction of Tip with the T-cell tyrosine kinase Lck.

**Materials and Methods**

**Expression plasmids.** The native tip open reading frame of herpesvirus saimiri C488 was transferred from plasmid p8488PS (6) to the pEF vector (39). Individual tyrosine-to-phenylalanine substitutions (Y114F, Y127F, and Y155F) were generated by site-directed mutagenesis using primers containing the desired mutation and the pEF-Tip plasmid as a template. AU1 epitope-tagged tip sequences from plasmids pBKCMVAU-1-Tip (wild type [wt]), pBKCMVAU-1-Tip/CSKH (deletion of the 5’ end EDLOSFLFEKLK), pBKCMVAU-1-Tip/mSH3B (5 pioneer) (58, 59) mutated to ATAAALAA) or pBKCMVAU-1-Tip/AUSKHSMH3B (double mutant) (39) were transferred into the EcoRI and Xhol restriction sites of expression vector pCDNA (Invitrogen, Karlsruhe, Germany). For the expression of Tip with an amino-terminal hemagglutinin (HA) epitope, tip sequences were PCR amplified from plasmids pStBlueStpCTip (35) or pStBlueStpCTip-FFYF (pStBlueStpCTip with tyrosine-to-phenylalanine substitutions at amino acid positions 94, 114, and 155 of Tip) with primers generating BGII and KpnI restriction sites and ligation into pCDNA-HA-MH (61).

The CDNA sequence encoding the full-length human lck tyrosine kinase (the plasmid was kindly provided by R. M. Perlmutter, Seattle, WA) was subcloned into the pEF vector (39). The expression plasmid for the SH3 deletion mutant of Lck was generated by ligating the BglII/MscI-cleaved pFJ construct with two complementary oligonucleotides (5’ ACCTGGTGG 3’ and 5’ CCACAG GTTG 3’), thereby removing the coding sequences for amino acids 67 to 115. 

**Generation of recombinant viruses.** The herpesvirus saimiri C488 mutant HVS/Tip mSH3B (21) was obtained from J. U. Jung (Southborough, MA). All other virus recombinants were generated by a cosmid-based approach as described previously (35). The specific mutations in the LBD of the tip gene were introduced into pSTBlueStpCTip141HN by insertion of Xhol-Stul fragments excised from the pBKCMVAU-1-Tip plasmids (39). Furthermore, tyrosine residue 127 was replaced by phenylalanine through PCR mutagenesis of plasmid pSTBlueStpCTip using the oligonucleotides y127f1 (5’ GAAACAGCTGTCGA GTGTGTTAGC-3’) and y127f2 (5’ CACATTTGAGACGCGACGCGG-3’). Mutated Bst1107I fragments were reinserted into cosmId 331, which was then used to reconstitute replication-competent viral genomes as described previously (35).

**DNA sequence analysis.** Nucleotide sequences of expression plasmids and virus recombination intermediates were determined with an ABI PRISM 3100 Genetic Analyzer according to the manufacturer’s instructions (Applied Biosystems, Darmstadt, Germany). DNA sequence evaluation was done with the GAP4 software (Staden Package [14]).

**Cell culture and transfection.** OMK cells (ATCC CRL1556) were used to propagate herpesvirus saimiri. The cells were cultivated in Dulbecco’s modified Eagle’s medium supplemented with glutamine (350 μg/ml), gentamicin (100 μg/ml), and 10% heat-inactivated fetal calf serum (FCS) (Biochrom, Berlin, Germany). Virus stocks were generated by infection of confluent OMK cells at a low multiplicity of infection.

Human lymphocyte cultures were grown in RPMI 1640 (Invitrogen) and Penasein 401 medium mixed at a ratio of 1:1 supplemented with 10% irradiated PCS (Biochrom, Berlin, Germany). Virus stocks were generated by infection of confluent OMK cells at a low multiplicity of infection.

Human lymphocyte cultures were grown in RPMI 1640 (Invitrogen) and Penasein 401 medium mixed at a ratio of 1:1 supplemented with 10% irradiated PCS (Pan Biotech, Aidenbach, Germany), glutamine (350 μg/ml), and gentamicin (100 μg/ml). *Callithrix jacchus* T-cell lines were transformed by herpesvirus saimiri wild-type strain C488 (17) or by mutant HVS/Tip mSH3B, kindly provided by J. U. Jung (21), were maintained in a mixture of 50% CMG medium (Vitromex, Sellers, Germany) and 50% RPMI 1640 medium containing 10% FCS. Jurkat clone E6-1 cells (ATCC TIB-152) were maintained in RPMI 1640 supplemented with 10% FCS. For transient transfection, 10^6 Jurkat cells were transfected with 30 to 95 μg plasmid DNA, electroporated by a single pulse of 250 V and 1,500 μF, and harvested after 24 to 48 h (EasyJet; Equibio). COS-7 cells (27) were grown in Dulbecco’s modified Eagle’s medium containing 10% FCS. A DEAE-dextran procedure was used for transient transfection (62). Transfected COS-7 cells were grown for 24 to 48 h; washed twice with...
Results

Contributions of CSKH and SH3B motifs to Tip-Lck interaction. An early study indicated that binding of Tip to Lck depends on both the CSKH and the SH3B motifs and that mutation of either motif abrogates kinase interaction (39). Recombinant herpesvirus saimiri C488 mutated at the SH3B motif of Tip (HVS/Tip mSH3B) induced enhanced proliferation, suggesting that Tip-Lck interaction is not essential for T-cell growth transformation (21). However, a more recent study demonstrated residual Lck binding of Tip mutated at the SH3B motif when both proteins were coexpressed in 293 cells (31). To test for this residual binding in T cells, we infected monkey lymphocytes with C488 wild type or the mutant HVS/Tip mSH3B (21). Both viruses induced lymphocyte proliferation, and the cultures were expanded until sufficient material was available for further analysis. Phosphorylated proteins were separated by SDS-PAGE and visualized by autoradiography (Fig. 1A). Autophosphorylated Lck was detected equally in Lck precipitates from both cell lines and at a slightly reduced level upon precipitation of wild-type Tip. The intensity of the Lck band in the Tip mSH3B precipitate was hardly above background. Phosphorylated Tip was detectable in the Lck and Tip precipitates from wild-type-infected cells. However, signals above background were also observed upon infection with HVS/Tip mSH3B, suggesting that residual Lck binding and phosphorylation of the Tip mutant is also present in these transformed T cells.

To further characterize LBD-dependent Lck-Tip interaction in lymphocytes, we transiently transfected Jurkat T cells with expression plasmids coding for Tip wild type or mutated at either the CSKH or the SH3B motif. CD4-, Lck-, and Tip-specific immune complex kinase assays revealed Lck interaction and phosphorylation of all Tip variants (Fig. 1B). The strongest signals were observed for the wild-type protein, but in spite of the reduced expression levels (Fig. 1B, bottom), relatively strong phosphorylation signals suggested residual Lck binding of both mutants in this T-cell system. However, the design of this assay did not allow discrimination between binding and phosphorylation of Tip and, due to high levels of endogenous Lck, may have been influenced by tyrosine phosphorylation of Tip in vivo.

To test for the relative roles of the SH3B and CSKH motifs in Lck interaction independently of the tyrosine phosphorylation of Tip that occurs upon coexpression of both proteins, we used an in vitro binding assay. For this purpose, COS-7 cells were individually transfected with Tip wt, ΔCSKH, mSH3B, or ΔCSKH mSH3B, as well as Lck wt and Lck ΔSH3. Lysates of transfected cells were adjusted for both equal total cellular protein content and equal Tip or Lck levels by the addition of lysates from nontransfected COS-7 cells. The binding of Tip and its mutants was assessed by Lck immunoprecipitation from mixed lysates, followed by an in vitro kinase assay and immunoblot detection of coprecipitated Tip proteins (Fig. 2). A correlation between phosphorylation and coprecipitation of Tip was observed in all samples. Therefore, phosphorylation of Tip and its mutants appeared to depend only on Lck binding and not the presence of specific residues within the CSKH or
SH3B motifs. Wild-type Tip binding and phosphorylation were detected in Lck and to a lesser extent in Lck\(\Delta\)SH3 precipitates, indicating that SH3-independent binding was detectable in this system. Relative to wild-type Tip, binding of the mutants Tip\(\Delta\)CSKH and Tip mSH3B to wild-type Lck was reduced, demonstrating the modular nature and the cooperation of the LBD motifs. Interaction of Tip\(\Delta\)CSKH with wild-type Lck, but not with the SH3 deletion mutant, indicated that SH3-independent binding relied on the CSKH motif, while comparable binding of Tip wild type and mSH3B to Lck\(\Delta\)SH3 confirmed the SH3 specificity of the SH3B motif. The involvement of additional Tip sequences in Lck interaction under these experimental conditions was excluded by the double mutant Tip\(\Delta\)CSKH mSH3B, which was devoid of any Lck binding activity.

**Transformation of human T cells by recombinant viruses expressing Tip LBD mutants.** We next wanted to study the relative roles of the cooperating LBD motifs, CSKH and SH3B, in the transformation of human T lymphocytes by herpesvirus saimiri C488. Therefore, mutations within the LBD were introduced into the viral genome by a well established,
cosmid-based procedure (Fig. 3) (35, 68). The resulting recombinant viruses encoded the same Tip mutants as the expression plasmids used in the previous experiments and were accordingly designated herpesvirus saimiri C488 ΔCSKH, mSH3B, and ΔCSKH mSH3B. The mutant C488 mSH3B encodes the same proline-to-alanine substitutions in Tip as HVS/Tip mSH3B (21). Human CBL were infected with wild-type C488, cosmid-generated wild-type M11 control virus, or the recombinant Tip-mutated viruses and monitored for growth transformation as detailed in Materials and Methods. While uninfected control cells were not growing during the observation period, all infected cultures initially displayed spontaneous proliferation (see Fig. 5). Morphological differences among the cultures were documented 5 weeks postinfection, when most of the control cells were dead. Cultures infected with wild-type or ΔCSKH viruses contained aggregates of viable cells. These aggregates were much larger in the cultures infected with the mSH3B mutant virus. The double-mutant herpesvirus saimiri C488 ΔCSKH mSH3B induced smaller aggregates, and these cultures contained large amounts of cell debris (Fig. 4A). Subsequent fluorescence-activated cell sorter analyses identified cells from all infected cultures as T cells expressing CD3, as well as CD4 and/or CD8, at their surfaces (Fig. 4B). Cultures infected with virus mutants lacking the CSKH motif stopped growing approximately 4 weeks after infection, while cells infected with the mSH3B virus ceased to proliferate only after 7 to 8 weeks (Fig. 5). These data suggest that viruses with mutations in the LBD of Tip retain their capability for initial T-cell stimulation, which is extended in the presence of the CSKH motif. However, none of the LBD mutant viruses supported long-term T-cell proliferation. Thus, growth transformation of human T lymphocytes by herpesvirus saimiri C488 depended on Tip-Lck interaction via both the SH3B and CSKH motifs. Mutation of either of these motifs resulted in loss of the transforming capacity.

Tyrosine phosphorylation and Lck interaction of Tip mutated at the conserved tyrosine residues. An additional Tip-Lck interaction site was supported by biophysical binding assays with Tip phosphopeptides, in which the phosphorylated tyrosine residue 127 of Tip-C488 was identified as a high-affinity ligand for the SH2 domain of Lck (4). The corresponding tyrosine residue 85 of Tip-C484 had been reported to be phosphorylated by Lck (32), but its role in kinase interaction and in T-cell transformation has not been analyzed. To test for the relevance of Tip’s tyrosine phosphorylation, which we had consciously excluded in our in vitro binding assay (Fig. 2), Jurkat T cells were transiently transfected with plasmids coding for wild-type or mutated Tip-C488. The variants Tip Y114F, Tip Y127F, and Tip Y155F carry individual phenylalanine sub-
stitutions at the three conserved tyrosine residues of Tip (Fig. 6, left); in the HA-tagged mutant FFYF, only the tyrosine residue at position 127 is conserved (Fig. 6, right). Tip was immunoprecipitated from the lysates of these cells and analyzed for tyrosine phosphorylation by immunoblotting (Fig. 6A). Tyrosine-phosphorylated Tip was detected in the lysates of all Tip-transfected cells. A strong reduction relative to the respective wild-type Tip was observed for mutant Y127F, but not for mutant FFYF, indicating that residue Y127 represents the major tyrosine phosphorylation site of Tip in Jurkat T cells. A minor difference in the migration of Tip Y114F observed in the phosphotyrosine blot, but not in Tip-specific immunoblots, suggests a Y114-dependent modification that remains to be characterized. Phosphoproteins coprecipitated with Tip, including a major band comigrating with Lck at 55 to 60 kDa, showed no difference with respect to the tyrosine mutants of Tip. Lck immune complexes contained equal amounts of wild-type and mutant Tip, but tyrosine phosphorylation was again specifically diminished on Tip Y127F (Fig. 6B). Differences in Lck-associated phosphoproteins and in the phosphorylation status of Lck were observed in cells transfected with Tip versus vector plasmids, but not among Tip and its mutants. These experiments indicate that the major tyrosine phosphorylation site of Tip, which had been described as a potential ligand for Lck SH2, does not enhance Tip-Lck interaction in the presence of an intact LBD.

Transformation of human T cells by a virus coding for the Tip mutant Y127F. Although no influence on Lck binding was detected in our previous assay, tyrosine phosphorylation of Tip might well have an impact on T-cell transformation by herpesvirus saimiri C488, e.g., by affecting Lck function or by changing the composition of Tip-Lck complexes. Therefore, we constructed a herpesvirus saimiri recombinant coding for Tip Y127F instead of the wild-type protein. Mutant virus was used for in vitro transformation assays with human cord blood lymphocytes, along with wild-type virus as a positive control and uninfected cells as a negative control. Cells were cultured and monitored for 15 weeks (Fig. 7). In the presence of exogenous IL-2 (left three columns), all infections with both wild-type and Y127F virus resulted in cell proliferation. An approximately 10-fold reduction of total cell numbers was observed for the mutant virus; however, overall deviations showed an even wider range. The presence of live cells in 1 out of 10 uninfected negative controls suggested that the cutoff for efficient transformation should be at an extrapolated cell number of $10^7$ by the end of the observation period. Indeed, all cells proliferating in response to viral infection exceeded this limit. Taken together, these data indicated that recombiant herpesvirus saimiri C488-Y127F was still capable of transforming human T cells to antigen-independent growth. To test for more subtle differences, the transformation assay included parallel samples that were not treated with exogenous IL-2 (Fig. 7, right three columns). Under these conditions, 5 out of 10 samples infected
with wild-type virus yielded proliferating cell lines by the end of the observation period. In contrast, no transformed cell lines were established with the Y127F mutant virus when exogenous IL-2 was omitted from the culture medium. Thus, transformation by wild-type herpesvirus saimiri is possible in the absence of exogenous IL-2 but is enhanced by its addition. The strict dependence of the mutant virus on IL-2 supplementation suggests a link between IL-2 signaling pathways and the major tyrosine phosphorylation site at position 127 in Tip, which may contribute to virus-induced T-cell proliferation.

**DISCUSSION**

The Src family tyrosine kinase Lck is an essential transducer of signals initiated by ligation of the T-cell receptor complex. The discovery of its interaction with the oncoprotein Tip of herpesvirus saimiri subgroup C strains prompted speculations about the role of Lck in viral T-cell transformation and oncogenesis (7, 49). However, a first study with recombinant herpesvirus saimiri C488 expressing a Tip mutant impaired in Lck binding indicated that kinase interaction is not required for immortalization of common marmoset (Callithrix jacchus) lymphocytes in vitro or for induction of lymphoma in this species (21). The mutation in the virus used in this study affected only the SH3B, but not the CSKH, motif in the LBD of Tip so that residual Lck engagement by the encoded Tip mutant was still possible (31). Furthermore, an interaction of phosphorylated tyrosine residue Y127 of Tip with the SH2 domain of Lck had not been taken into consideration (4).

We now asked what was the role of the individual Tip-Lck interaction sites in growth transformation of primary human T cells, a feature unique to herpesvirus saimiri subgroup C strains. Although residual Lck binding was observed when either the CSKH or SH3B sequence was mutated, both motifs in the LBD of Tip were found to be essential for transformation in this system. The enhanced initial proliferation of cells infected with the mSH3B recombinant virus suggests a specific role of the CSKH or SH3B sequence in growth transformation of primary human T cells. The implicit selective pressure for all Lck interaction sites points to an essential function in the natural host whose nature remains enigmatic.

Another effect of Tip that has to be considered for its involvement in viral transformation is the downregulation of surface receptor molecules. High levels of stable or transient Tip expression in Jurkat T cells, but not in an Lck-negative Jurkat variant, led to modulation of the TCR-CD3 complex and of the coreceptor CD4 (40, 59). This process is enhanced when tyrosine residue 114 of Tip is replaced by serine and involves binding of Tip to the lysosomal targeting protein p80 (58, 59). However, the lower levels of Tip expression in herpesvirus saimiri C488-transformed cells do not seem to be sufficient for overt receptor downregulation. Surface expres-

...
sion of CD4 is normal, and CD3 is only modestly reduced in lymphocytes infected with herpesvirus saimiri C488 wild type compared to transformation-competent mutants (Fig. 4). Another minor decrease in CD3 expression is observed in C488-Y114F cells relative to wild-type transformed cells (35). Therefore, only a small fraction of TCR-CD3 complexes is likely to be endocytosed and degraded in virus-transformed lymphocytes and may not have a detectable impact on Lck expression levels and on basal, as well as inducible, cellular protein tyrosine phosphorylation, which was strongly reduced upon Tip overexpression (29, 40, 58, 59). Likewise, the Tip-induced block in signaling from Lck to ZAP70 (11) may not affect all TCR-CD3 complexes on the surfaces of transformed cells. These assumptions are supported by one of the most intriguing properties of human T-cell clones transformed by herpesvirus saimiri C488, the maintenance of antigen specificity and responsiveness (9, 15, 65). The transformed T-cell clones also display increased basal levels of cellular protein tyrosine phosphorylation relative to their noninfected parental lines (67). In conclusion, Tip-mediated downregulation of TCR expression and signaling is not likely to be essential for T-cell transformation.

Modulation of the TCR-CD3 complex from the surfaces of Jurkat T cells is an Lck-dependent process that may be induced by the expression of constitutively active Lck (19). Therefore, TCR-CD3 downregulation by Tip indicates Lck activation in T cells expressing the viral oncoprotein. While negative regulatory downstream effects seem to mask this activation in T cells overexpressing Tip, it has been demonstrated in several other cellular and in vitro systems (31, 42, 48, 51, 67). Dependent on the presence of both the CSKH or SH3B motifs, Tip is able to activate Lck in an in vitro assay system even when the regulatory tyrosine residues Y394 and Y505 of Lck are mutated (33). This novel type of Lck regulation by simultaneous binding of both LBD motifs may result in an altered substrate specificity of the kinase, contributing to the abrogation of ZAP70 phosphorylation (11). More importantly, this dysregulation may link Tip-bound Lck to alternative downstream effectors, which may account for the substitution of ZAP70 function by herpesvirus saimiri C488 (54). Therefore, the characterization of substrates specific for Tip-complexed Lck will be an important step to identify cellular proteins mediating the essential functions downstream of Tip-Lck interaction.

In summary, our data provide evidence that a complex interaction between the viral oncoprotein Tip and the T-cell tyrosine kinase Lck is required for transformation of human T cells by herpesvirus saimiri C488. However, known downstream targets of Tip, STAT activation, TCR modulation, and blocking of ZAP70 activation, can be excluded as mediators of the transforming effects. Consequently, future investigations will have to address in more detail the Lck signal transduction pathways in herpesvirus saimiri-transformed human T cells.
