Cytotoxic-T lymphocyte (CTL) responses to epitopes in alternative HIV reading frames have been reported. However, the extent of CTL responses to putative proteins encoded in antisense reading frames is unknown. Using sequence alignments and computational approaches, we here predict five potential antisense HIV proteins and characterize common CTL responses against them. Results suggest that antisense-derived sequences are commonly transcribed and translated and could encode functional proteins that contain important targets of anti-HIV cellular immunity.

Virus-specific CD8+ cytotoxic-T lymphocyte (CTL) responses are important in the control of HIV infection (1–3). Accumulating evidence indicates that in addition to CTL responses targeting known structural and nonstructural HIV proteins, CTL responses to epitopes in alternative reading frames (ARFs) of HIV can contribute to in vivo immune selection pressure (4–6). Importantly, these CTL responses are not limited to ARFs in the sense direction, but may also target antisense-encoded ARFs (5, 6). Antisense transcription of known host genes in human and rodent cells has been extensively described (7–10), and the existence of fully translated antisense (ASRF) of Pol and the previously reported MPQ ASRF was demonstrated (11). To find immunological evidence that antisense-encoded MGS protein within the +1 antisense reading frame (ASRF) of Pol and the previously reported MPQ ASRF within the +1 ASRF of Env (11) (Fig. 2A and B). The remaining three putative ASRs, MAN, MLF, and MAL, were less frequently targeted, with three, six, and nine responses, respectively (see Fig. S1 in the supplemental material). Responses to the two most commonly targeted OLPs, M27 (PLMGGAYIAFPTSC) and M49 (SVNCFTSLVWAPLILAYF, within MGS ASP, targeted by 11/40 subjects), were further characterized (Fig. 2B to D). Peptide titration analyses (Fig. 2C) were performed to (i) determine the functional avidity of the reactive T cells and (ii) rule out that the responses were artifacts of unspecified reactivities due to high peptide concentrations used in the screening assays (15, 16). The data show the peptide concentrations that elicited the half-maximum response (SD 50%) that were consistent with what chronically HIV-infected subjects and 20 HIV-uninfected controls, were tested. Responses to the ASP-derived OLPs were detected exclusively in HIV-infected persons (15 of 40 [37.5%] showed reactivities to at least one OLP) and targeted all five putative ASPs. Most (n = 22 [30%] and n = 24 [36%], respectively, of 66 responses in total) were detected against the previously undescribed antisense-encoded MGS protein within the +1 antisense reading frame (ASRF) of Pol and the previously reported MPQ ASP within the +1 ASRF of Env (11) (Fig. 2A and B). The remaining three putative ASPs, MAN, MLF, and MAL, were less frequently targeted, with three, six, and nine responses, respectively (see Fig. S1 in the supplemental material). Responses to the two most commonly targeted OLPs, M27 (PLMGGAYIAFPTSC) and M49 (SVNCFTSLVWAPLILAYF, within MGS ASP, targeted by 11/40 subjects), were further characterized (Fig. 2B to D).

would be expected for responses to epitopes in standard ORFs. To further demonstrate the potential HLA class I restriction of the MPQ-M27 and MGS-M49 responses, flow cytometry-based HLA restriction analyses were performed (4), identifying HLA-B*35:01 and HLA-C*04:01 as potential restricting elements and showing that responses were mediated by CD8^+/H11001^ T cells (Fig. 2D and E).

While the data suggest that these immunodominant antisense-encoded epitopes are targeted by CD8 T cells, we cannot exclude that some of the observed responses against antisense-encoded OLPs may be CD4 T cell mediated.

To further support the notion that ASPs were expressed and can be targeted by host T cells, we subjected the five ASP sequences to a CTL epitope prediction analysis, using the “Epipred” algorithm trained on well-characterized CD8^+/H11001^ T cell epitopes from the Immune Epitope Database (IEDB) and the Los Alamos HIV database (17). Epipred predicts epitopes based on scores determined by the probability of binding to respective HLA molecules, also considering the presence of specific epitope-flanking regions. For instance, a prediction score of 0.98 indicates a 98% probability that the predicted epitope indeed can be presented and recognized by a T cell. Based on the HLA type of each screened individual and OLP pair, we determined the best epitope (i.e., the epitope with the highest prediction score) for each response by testing all 8 to 11mers embedded within the OLP sequence against all six HLA class I alleles of the responding subject. As expected, several individuals who responded to the same OLP likely did so through the same HLA-epitope pair. Interestingly, the median posterior probability score for the best-predicted epitopes was significantly higher for those OLPs that were in fact targeted in the ELISpot screens compared to the nontargeted OLPs (P = 0.004) (Fig. 3A). Similarly, the distribution of best-predicted epitopes per OLP and subject showed an enrichment of epitopes with elevated prediction scores in targeted OLPs compared to those in nontargeted OLPs (Fig. 3B), thus supporting a direct link between high epitope prediction score and ELISpot reactivity. These findings are further validated by the Epipred predictions for the two most immunodominant OLPs, M49 and M27, when not only the best-, but all, predicted epitopes were considered. In the case of M49, Epipred predicted CFTSLVWAPLI (CI-11) as an HLA-C*04-restricted epitope with a prediction score of 0.90 (Fig. 3C) and NCFTSLVWAPL (NL-11) as a putative HLA-C*01 and C*07 epitope (posterior probabilities of 87% and 83%, respectively), in line with the fact that 8 out of the 11 M49 responders expressed at least one of these HLA class I alleles. With lower probability, Epiprep also predicted a putative HLA-B*35:01-restricted epitope, APLILAYFPVF (AF-11; score of 0.51), still in line with three of the M49 responders expressing HLA-B*35:01. Similarly, in the case of OLP M27, Epipred predicted AYIAFPTSCHM (AM-11) as being HLA-C*0401 restricted, which is consistent with three out of seven responders expressing this allele. The detection of additional OLP-specific responses in individuals not expressing the predicted HLA alleles is in agreement with the possible presence of additional CTL.

FIG 1 Sequences and localization of putative antisense proteins (ASP) in the HIV genome. (A) The full-length HIV genome is shown with structural and accessory proteins encoded in the three regular open reading frames (ORFs). Black boxes depict the location of the five predicted ASPs relative to the regular ORFs. (B) The consensus amino acid sequences of the five predicted proteins are shown. Their antisense reading frames (ASRFs) and the frequencies at which they were found among 355 HIV isolates are indicated. *, stop codon.
Peripheral blood mononuclear cells (PBMCs) were tested in ELISpot assays for reactivity against overlapping peptides at a peptide concentration of 28 μg/ml as described previously (4). Responses of >50 spot-forming cells per million (SFC/M) PBMCs were considered positive. (A) The breadths (i.e., number of responses per tested individual) of the two most frequently targeted ASPs, MPQ (upper panel) and MGS (lower panel), are displayed. None of the HIV-negative controls showed a response to any of the peptides tested. (B) Magnitudes (SFC/M PBMCs using single peptides) of the positive responses targeting MPQ (upper panel) or MGS (lower panel) are indicated. (C) Peptide titrations (ranging from 100 μg/ml to 0.001 pg/ml) were performed on unexpanded PBMCs to determine the functional avidity (SD 50%) of responses targeting M27 (upper panel) and M49 (lower panel). (D) Partially HLA-matched B cell lines were peptide pulsed (M27, upper panel; M49, lower panel) and incubated with peptide-specific expanded T cells from HIV-infected individuals. Black bars indicate the IFN-γ response as assessed by flow cytometry; white bars indicate the background response (media alone). The indicated HLA alleles represent alleles matched between antigen-presenting cells and the T cell line (TCL) reactive with the tested peptide. Values are expressed as percent IFN-γ+ CD8+ T cells after stimulation for 5 h. (E) Intracellular cytokine staining following incubation for 5 h with M27 (upper panel) or M49 (lower panel), with peptides directly added to the T cell lines, confirmed the phenotype of the responding cells as CD8+ T cells. Panels show peptide-specific T cell lines stimulated with media alone (left) versus with peptide (right). The percent IFN-γ+ cells is indicated. Experiments for panels D and E were performed at different time points, resulting in different maximal responses.
epitopes in this OLP sequence or epitopes with a wide HLA promiscuity (18). Overall, the epitope prediction analyses provide further evidence that OLP responses were mediated by HLA-I-restricted T cells and provide specific candidate epitopes that may drive these responses.

Together, the present data identify five potential ASP sequences in HIV which are relatively frequently targeted by T cells in HIV-infected subjects. Thus, these data (i) strongly support the expression and translation of these proteins in HIV infection and (ii) identify additional T cell targets that may contribute to host...
immune control of HIV. Relative to their length and the frequency whereby they are targeted, responses to these ASPs compare well with observed reactivities to epitopes encoded in forward cryptic HIV reading frames (4) and response rates to well-studied regulatory HIV proteins, such as Tat, Vif, and Rev (19). The response rates are also comparable to activities reported by Champiat et al., who identified responses to ASPs that partially overlapped with four of our ASP sequences (6). Together, the present study corroborates earlier reports of responses to epitopes in alternative HIV reading frames and suggests that HIV may express several additional, relatively conserved proteins that may be under evolutionary constraints and thus exert hitherto-unknown functions.
