In the canonical STAT3 signaling pathway, binding of agonist to receptors activates Janus kinases that phosphorylate cytoplasmic STAT3 at tyrosine 705 (Y705). Phosphorylated STAT3 dimers accumulate in the nucleus and drive the expression of genes involved in inflammation, angiogenesis, invasion, and proliferation. Here, we demonstrate that human cytomegalovirus (HCMV) infection rapidly promotes nuclear localization of STAT3 in the absence of robust phosphorylation at Y705. Furthermore, infection disrupts interleukin-6 (IL-6)-induced phosphorylation of STAT3 and expression of a subset of IL-6-induced STAT3-regulated genes, including SOCS3. We show that the HCMV 72-kDa immediate-early 1 (IE1) protein associates with STAT3 and is necessary to localize STAT3 to the nucleus during infection. Furthermore, expression of IE1 is sufficient to disrupt IL-6-induced phosphorylation of STAT3, binding of STAT3 to the SOCS3 promoter, and SOCS3 gene expression. Finally, inhibition of STAT3 nuclear localization or STAT3 expression during infection is linked to diminished HCMV genome replication. Viral gene expression is also disrupted, with the greatest impact seen following viral DNA synthesis. Our study identifies IE1 as a new regulator of STAT3 intracellular localization and IL-6 signaling and points to an unanticipated role of STAT3 in HCMV infection.

Human cytomegalovirus (HCMV) is a human herpesvirus that infects the majority of the world population. Primary exposure results in a lifelong infection. HCMV is an opportunistic pathogen that causes serious disease in immunocompromised patients and is a leading cause of congenital birth defects (1, 2). The current FDA-approved antiviral compounds inhibit viral DNA replication and have significantly improved the management of HCMV-associated diseases. Although the use of antivirals usually resolves viremia, the compounds fail to remove the latent reservoirs of HCMV within the body. Moreover, their use is limited due to toxicity, poor oral bioavailability, and the selection of antiviral-resistant variants (3–5). Efforts are under way to identify additional antiviral compounds to increase treatment options.

The 72-kDa immediate-early 1 (IE1) protein of HCMV is a key regulatory phosphoprotein conditionally required for viral early gene expression and replication in fibroblasts (6–8). IE1 localizes to the host cell nucleus, targeting both interchromatin compartments termed nuclear domain 10 (ND10) (9–11) and chromatin (12). Our work and a consecutive study by Huh et al. have demonstrated that IE1 forms physical complexes with STAT1 and STAT2 in the nuclei of infected cells, prevents association of STAT1, STAT2, and interferon (IFN) regulatory factor 9 with promoters of type I IFN-stimulated genes, and inhibits IFN-α-induced transcription (13–15). Consequently, IE1 disrupts type I IFN-dependent STAT signaling, endowing the virus with partial resistance to the antiviral effects of IFN-α and IFN-β (13–15). Notably, this activity was subsequently shown to be conserved across IE1 homologs of the human betaherpesvirus subfamily (16). Conversely, following ectopic expression in an inducible cell model (TetR/TetR-IE1), IE1 elicited a transcriptional response dominated by the upregulation of proinflammatory and immune-modulatory genes normally induced by IFN-γ (17). Although IE1-mediated gene expression proved to be independent of IFN-γ, it requires the tyrosine-phosphorylated form of STAT1. Accordingly, STAT1 accumulates in the nucleus and becomes associated with IE1 target genes upon expression of the viral protein (17).

Another member of the STAT protein family, STAT3 is involved in regulating diverse responses. In total, four isoforms of STAT3 have been identified: full-length STAT3α and truncated STAT3β, STAT3γ, and STAT3δ (for a review, see reference 18). Although the functions of the truncated isoforms are unclear, studies are beginning to suggest that they have distinct cellular activities from STAT3α (19–21). STAT3 is activated by a variety of different stimuli, including interleukin-6 (IL-6) and other cytokines and growth factors (18,22). In the canonical STAT3 signaling pathway, binding of agonist to receptors activates Janus kinases (JAKs), which phosphorylate cytoplasmic STAT3 at tyrosine 705 (Y705). Phosphorylated STAT3 dimers accumulate in the nucleus and drive the expression of genes involved in inflammation, angiogenesis, invasion, and proliferation (18,22). Nuclear translocation is mediated by the importin-α and -β1 heterodimer complex (23,24). Furthermore, phosphorylation at serine 727 (S727) is necessary for maximal STAT3 transcriptional activity (25,26). Recent studies have demonstrated that STAT3 when unphosphorylated is necessary for maximal STAT3 transcriptional activity (25,26).
lated at Y705 shuttles between the cytoplasm and the nucleus and is also transcriptionally active (27–30).

In this study, we determined a mechanism used by HCMV to regulate STAT3 during infection. We demonstrate that HCMV IE1 is both necessary and sufficient to promote early nuclear localization of STAT3, which is predominately unphosphorylated at Y705. One functional consequence of the IE1-mediated disruption of STAT3-mediated IL-6 signaling. In addition, we found that inhibition of STAT3 nuclear localization is linked to reduced viral DNA replication and late gene expression.

MATERIALS AND METHODS

Biological reagents. MRC-5 fibroblasts, ARPE19 epithelial cells, and U373 astrocytoma cells were propagated in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 7% fetal bovine serum (FBS; Life Technologies, Carlsbad, CA) and 1% penicillin-streptomycin (Life Technologies). Unless otherwise stated, cells were grown until confluent, serum starved in 0.5% fetal bovine serum for 2 days, and then infected at a multiplicity of infection ranging from 0.25 to 5 infectious units (IU) per cell in DMEM supplemented with 0.5% FBS. In several experiments, cells were treated 24 h prior to infection with inhibitors: 15 μM curcumin (Sigma-Aldrich, St. Louis, MO), 30 to 150 μM S3i-201 (NSC 74859; ThermoFisher Scientific, Waltham, MA), 5 μM Statc (Santa Cruz Biotechnology), 4 μM WP1066 (Santa Cruz Biotechnology), or dimethyl sulfoxide (DMSO; Sigma). Compounds were replaced every 24 h. As a control for pSTAT3- and STAT3-regulatable gene expression, U373 cells were treated with 183 ng/ml of carrier-free recombinant human IL-6 (BioLegend, San Diego, CA) for 15 min for Western blot analysis or for 45 min for gene expression studies. Studies using MRC-5 cells also included recombinant human IL-6 receptor alpha (IL6R); R&D Systems, Minneapolis, MN), TetR-IE1 and TetR cells have been previously described (17) and were treated with doxycycline (Dox) for 10 h at 72 h after a single concentration of 1 μg/ml. Viability and total cell numbers were determined with Viacount (EMD Millipore, Billerica, MA) and a Gauva EasyCyte miniflow cytometer (Millipore). Control small interfering RNAs (siRNAs; Cell Signaling Technology), siRNA targeting importin-β1 (Life Technologies), or siRNA targeting STAT3 (On Target Smart pool; ThermoFisher) were transfected using Lipofectamine 2000 (Life Technologies).

Bacterial artificial chromosome (BAC)-derived HCMV strains AD169 (Advt) (31), Adin27F (32), and Towne wild type (wt) (33) were propagated in primary fibroblasts, and Towne dIE1 virus (14) was propagated in TetR-IE1 cells. BAC-derived HCMV clinical virus TB40/E (34) was propagated in ARPE19 epithelial cells. Viral titers were determined in an infectious units assay (35) or a standard plaque assay.

Analysis of protein, DNA, and gene expression. Preparation of cell extracts, immunoprecipitation, Western blot analysis, and immunofluorescence microscopy were completed as previously described (14, 32, 36). The antibodies used are listed below. Immunofluorescence was observed with a 63× lens in a Leica DMRX inverted microscope (Leica Microsystems, Wetzlar, Germany) equipped with a Retiga-SRV digital camera and Image-Pro Plus 6.2 software (Q-Imaging, Surrey, Canada) (see Fig. 3 and 5, below; see also Fig. S2 in the supplemental material). Alternatively, a 60× lens in an Eclipse Ti-U inverted microscope (Nikon, Melville, NY) equipped with a CoolSNAP ES2 charge-coupled-device camera (Photometrics), multiphoton laser scanning confocal microscope (Leica Microsystems), and NIS-Elements software (Nikon) were used for image analysis (see Fig. 1, 2, 6, and 8, below; see also Fig. S1 in the supplemental material). The mean fluorescent intensities of STAT3 within the nucleus and cytoplasm were obtained from an average of 20 to 30 cells and from at least two replicate experiments unless otherwise stated. The data are presented as the nuclear-to-cytoplasmic ratio (N/C) ± the standard error of the mean (SEM). Viral DNA content and RNA expression from infected cells were determined using quantitative or quantitative reverse transcriptase PCR (qPCR or qRT-PCR), respectively, as previously described (14, 32) with the primers listed below. Quantities for unknown samples were

RESULTS

HCMV infection localizes unphosphorylated STAT3 to the nucleus and disrupts IL-6-induced gene expression. Limited information is available on the impact of HCMV infection on the cellular transcription factor STAT3. To determine whether HCMV infection limits STAT3 nuclear localization and reduces IL-6 signaling, we first determined that STAT3 translocation is linked to reduced viral DNA replication and late gene expression.

Antibodies. The following antibodies were used in these studies: normal rabbit IgG (Sigma-Aldrich), mouse anti-FLAG M2 (Sigma-Aldrich), mouse anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (Santa Cruz Biotechnology), rabbit anti-STAT3 (On Target Smart pool; ThermoFisher) were used in all experiments. The antibodies against HCMV proteins were mouse anti-pUL123 clone 1B1, mouse anti-pUL122 clone 3A9, mouse anti-pTRS1, mouse anti-pUL99, mouse anti-pUL37 clone 2A1D, mouse anti-pUL38 clone 3D12 (generously provided by Tom Shenk, Princeton University), and mouse anti-pUL44 (Viruses). Secondary antibodies included goat anti-mouse–horse-radish peroxidase (HRP) and donkey anti-rabbit–HRP (Jackson ImmunoResearch) conjugates for Western blot analysis and anti-mouse–Alexa Fluor 488, anti-mouse–Alexa Fluor 568, anti-mouse–Alexa Fluor 594, anti–rabbit–Alexa Fluor 488 (Life Technologies) conjugates, and Alexa Fluor 647 conjugated to anti-CD126 (IL-6R; Biolegend, San Diego, CA) for immunofluorescence. Cellular DNA was stained with 4′,6-diamidino-2-phenylindole (DAPI; Life Technologies).

PCR oligonucleotides. The following oligonucleotide pairs were used in these studies: IL-6 (5′-AGCCACTACCTGTTTCAGAACGA-3′ and 5′-AGTGGCTTTTGCTTTTCACCAC-3′), SOCS3 (5′-ATCCGGCTTAACTGGTCTGTC-3′ and 5′-TGGCAATACCTATGCGTGAGGTCC-3′), pUL37 (5′-CTGCTGTAGCCAAATTCGT-3′ and 5′-ACCCTACGACGACGTCTTGCT-3′), GAPDH (5′-GACCCACTCTGCTCCTTTC-3′ and 5′-CTGTGCTGACCAAATTGCT-3′), and SOCS3 promoter (5′-GAAACCTCCTTCAAGACACAGG-3′ and 5′-CAACCACTGGCACGATATAG-3′). The following oligonucleotides were used in qPCR: 18S rRNA (5′-TTGAGAAGCCTGAGGTGAG-3′), GAPDH (5′-GACCCACTCTGCTCCTTTC-3′ and 5′-CTGTGCTGACCAAATTGCT-3′), and SOCS3 promoter (5′-GAAACCTCCTTCAAGACACAGG-3′ and 5′-CAACCACTGGCACGATATAG-3′).
influences STAT3, we evaluated subcellular localization at 2 and 24 h postinfection (hpi). We infected U373 astrocytoma cells by using HCMV strain AD169 (ADwt) at a multiplicity of infection (MOI) of 5 IU per cell in 0.5% serum. As a control, uninfected cells were treated with or without human IL-6 to stimulate phosphorylation of STAT3. Reduced serum conditions allowed for more robust IL-6-stimulated responses. Cells were fixed and stained using antibodies against STAT3 and pSTAT3 at Y705. To quantify changes in localization, we determined the N/C ratio of mean fluorescent intensities between nuclear and cytosolic staining. We detected increased STAT3 within the nuclei of infected cells at 2 hpi (N/C, 2.95 ± 0.05) and 24 hpi (N/C, 6.71 ± 0.68) compared to uninfected cells (N/C, 1.25 ± 0.16) (Fig. 1A). As expected, we observed increased nuclear localization of STAT3 (N/C, 3.42 ± 0.35) and pSTAT3 in mock-infected and IL-6-treated cells (Fig. 1A). To our surprise, we detected little to no pSTAT3 within the nuclei of infected cells (Fig. 1A). These data suggest that HCMV infection rapidly promotes nuclear localization of STAT3 in the absence of robust phosphorylation at Y705.

In general, phosphorylation of cytoplasmic STAT3 at Y705 occurs following cytokine and growth factor stimulation and results in STAT3 nuclear accumulation and DNA binding (18, 22). We next investigated whether HCMV influences STAT3 phosphorylation during both infection and cytokine stimulation. U373 cells were infected at an MOI of 5 IU/cell, and cultures were treated at the indicated times postinfection with or without IL-6 (Fig. 1B). We evaluated steady-state protein levels by using Western blot analysis on whole-cell lysates isolated from a population of cells. Compared to mock-infected cells treated with IL-6, HCMV infection suppressed IL-6-induced phosphorylation of STAT3 at Y705 by 2 hpi and continued through 48 hpi (Fig. 1B). In contrast, phosphorylation at Y727 occurred regardless of infection and was independent of IL-6 stimulation (Fig. 1B). At a lower MOI, we observed via Western blotting increased STAT3 phosphorylation at Y705, which likely occurs in uninfected cells in the population, as determined by immunofluorescence analysis (see Fig. S1 in the supplemental material). To determine whether the response also occurs when using a clinically relevant HCMV strain, we completed the experiment using the TB40/E virus (34). Similar to AD169, TB40/E infection suppressed IL-6-induced phosphorylation at Y705 but not Y727 (Fig. 1C). These data demonstrate that HCMV infection disrupts IL-6-induced phosphorylation of STAT3 at Y705.

We evaluated the impact of infection on the expression of two genes known to be regulated by STAT3, those for IL-6 and SOCS3 (18, 37). We infected U373 cells at 1 IU/cell using ADwt virus with or without IL-6 at the indicated times postinfection and determined changes in gene expression by using qRT-PCR relative to GAPDH RNA levels. Compared to mock controls, infection significantly decreased gene expression of IL-6 and SOCS3 following IL-6 stimulation (Fig. 1D). These data support the conclusion that HCMV infection disrupts expression of two IL-6-induced STAT3-regulated genes. To exclude the possibility that disruption of IL-6 signaling is a consequence of decreased IL-6 receptor cell surface expression, we measured the impact of infection on IL6Rα levels. We infected U373 cells at 3 IU/cell, and surface levels of IL6Rα were determined by flow cytometry. Compared to mock infection, we observed similar levels of IL6Rα during HCMV infection at 6 and 24 hpi (Fig. 1E). These data rule out the possibility of HCMV-mediated loss of endogenous IL6Rα surface expression during the time of altered gene expression.

To test whether HCMV-mediated inhibition of IL-6 signaling depends on STAT3 nuclear localization, we evaluated the effects on STAT3 phosphorylation after disruption of nuclear import. Nuclear translocation of STAT3 is mediated by the importin-α and -β1 heterodimer complex (23, 24). We transfected U373 cells with either a control siRNA or an siRNA targeting importin-β1 and observed a reduction in importin-β1 levels (Fig. 2A). Under these conditions, reduced importin-β1 resulted in increased pSTAT3 in IL-6-treated HCMV-infected cells (Fig. 2A). Furthermore, disruption of importin-β1 reduced IL-6-induced STAT3 nuclear accumulation in both mock-infected cells (N/C, 1.27 ± 0.11) and HCMV-infected cells (N/C, 1.55 ± 0.12) compared to control siRNA-treated mock-infected (N/C, 2.19 ± 0.03) and infected (N/C, 4.15 ± 0.10) cells (Fig. 2B). These data suggest that HCMV promotes nuclear accumulation of STAT3 early during infection, thereby moving STAT3 away from the cytosolic regulators.

Changes in STAT3 phosphorylation and localization are detectable as early as 2 hpi, indicating a role for HCMV virions or newly expressed proteins in manipulating STAT3. To identify the source of the activity, U373 cells were infected with either untreated ADwt or UV-irradiated virus and evaluated by immunofluorescence microscopy. STAT3 nuclear localization occurred following infection with untreated (N/C, 3.27 ± 0.15) but not UV-irradiated (N/C, 1.09 ± 0.02) virus (Fig. 2C). Under these conditions of UV treatment, we did not detect IE1 RNA expression (Fig. 2D). These data demonstrated that viral gene expression is necessary for relocation of STAT3.

HCMV IE1 promotes STAT3 nuclear accumulation and disrupts IL-6-induced STAT3 phosphorylation, DNA binding, and target gene expression. HCMV protein IE1 is known to regulate both STAT1 and STAT2 (13–15, 17). To determine whether IE1 expression could influence STAT3 localization, MRC-5 fibroblasts were mock infected or infected at 3 PFU/cell with either wild-type virus (wt) or an IE1-deficient virus (dIE1) of the HCMV Towne strain. Using immunofluorescence microscopy, we observed increased staining of STAT3 within the nuclei of IE2-positive infected cells by 6 hpi with wt virus (N/C, 1.73 ± 0.04) but not dIE1 (N/C, 0.99 ± 0.15) compared to mock-infected cells (N/C, 1.09 ± 0.13) (Fig. 3A). This increase was also observed at both 24 (N/C, 1.73 ± 0.55) and 72 hpi (N/C, 2.13 ± 0.56) (Fig. 3A). At these later times, we did observe a few cells in the dIE1 infections that had increased nuclear STAT3 staining; however, this was not significant among the population, as indicated by the N/C ratio determined from a random selection of cells (n = 95). These data demonstrated that IE1 is necessary for the efficient nuclear localization of STAT3 during infection. HCMV IE1 has been previously demonstrated to localize to mitotic chromatin (14). In cells undergoing mitosis in the infected population, we observed colocalization of STAT3 with DAPI-stained chromatin (Fig. 3B, left and right panels). Moreover, STAT3 and IE1 colocalized in wt- but not dIE1-infected cells (Fig. 3B, right panel). To assess a possible physical interaction between IE1 and STAT3, we isolated whole-cell lysates at 24 hpi and immunoprecipitated protein complexes by using an antibody against IE1. Following immunoprecipitation, we detected the slower-migrating STAT3α but not the smaller STAT3 isoform by Western blotting from Towne strain wt-infected cells (Fig. 3C). We did not observe an
FIG 1 Infection increases the levels of unphosphorylated STAT3 in the nucleus and inhibits IL-6-stimulated gene expression. (A) Serum-starved U373 cells were mock infected or infected with ADwt at 5 IU/cell in 0.5% serum. Samples were fixed at the indicated times, incubated with antibodies against STAT3 (green) and pSTAT3 at Y705 (red), and counterstained for DNA with DAPI (blue). Where indicated, mock samples were treated with IL-6 at 183 ng/ml. The mean fluorescent intensities of STAT3 within the nucleus and cytoplasm were obtained from an average of 20 to 30 cells and from at least two replicate experiments. The data are presented as the nuclear-to-cytoplasmic ratio ± the SEM. (B) Cells were infected as described for panel A and treated with IL-6 or DMSO for 15 min prior to Western blot analysis with the indicated antibodies. The α- and β-STAT3 isoforms were evident upon sufficient electrophoretic separation. (C) The above-described experiment was repeated using the clinical isolate TB40/E. (D) Cells were infected at 1 IU/cell and treated with IL-6 or DMSO for 45 min just prior to harvest at 24 and 48 hpi. Levels of the indicated mRNAs were quantified by qRT-PCR and are presented relative to GAPDH. Data represent two biological replicate experiments and are presented as the means ± SEM. *, P < 0.05. (E) Serum-starved U373 cells were infected as described for panel A. Cells were fixed, stained with anti-IL6R antibody conjugated to Alexa Fluor 647, and analyzed using flow cytometry. As a control, cells were treated with trypsin solution for 15 min prior to antibody staining (gray), and the values represent the mean fluorescence intensity from two biological experiments.
interaction when we used an antibody against IE2 or following infection by the dlIE1 virus (Fig. 3C). IE1 was also specifically detected throughout the viral infectious cycle (6 to 72 h) in protein complexes isolated by immunoprecipitation with a STAT3-directed antibody (Fig. 3D). These data demonstrate that HCMV IE1 associates with at least one STAT3 isoform during infection.

Finally, we evaluated the functional impact of IE1 on STAT3 following IL-6 stimulation. These studies were completed by adding both IL-6 and soluble IL-6 receptor alpha (IL-6/IL6Rα) to the culture medium, because MRC-5 cells are largely unresponsive to IL-6 alone. Following the addition of exogenous IL-6/IL6Rα, infection by wt but not dlIE1 virus resulted in reduced levels of Y705-phosphorylated STAT3 at 16 hpi compared to the mock group (Fig. 4A). Under these conditions in mock-infected cells, IL-6/IL6Rα triggered robust STAT3 DNA binding at the SOCS3 promoter and little binding at the SOCS3 transcribed region, as determined in a chromatin immunoprecipitation (ChIP) assay (Fig. 4B). During infection, IL-6/IL6Rα-induced STAT3 DNA binding was substantially diminished when we used wt virus but not with the dlIE1 virus (Fig. 4B). Concordantly, SOCS3 gene induction was significantly reduced during wt infection (Fig. 4C). Infection by the dlIE1 virus altered SOCS3 expression, but to a lesser degree than wt virus (Fig. 4C). Expression of HCMV IE2 was unaltered between the different conditions of infection (Fig. 4C). Our results support the conclusion that HCMV IE1 binds to STAT3α and is necessary to localize STAT3 to the nucleus at early times of infection. Furthermore, expression of IE1 disrupts IL-6-induced phosphorylation of STAT3, DNA association by STAT3, and SOCS3 gene induction during infection.

To determine whether IE1 expression is sufficient to mediate these changes, we induced IE1 in the absence of infection by using a tetracycline repressor-regulated expression system in human fibroblasts (TetR/TetR-IE1) (17). Following induction of IE1 expression using doxycycline, we observed strong accumulation of
FIG 3 HCMV IE1 interacts with STAT3 and promotes STAT3 nuclear accumulation. (A) Growth-arrested MRC-5 cells were mock infected or infected with wt or dIE1 at 3 PFU/cell in 10% serum. Samples were fixed at the indicated times, incubated with antibodies against STAT3 (green) and HCMV IE2 (red), and counterstained for DNA using DAPI (blue). Bar, 10 μm. The mean fluorescent intensities of STAT3 within the nucleus and cytoplasm were obtained from an average of 100 cells. The data are presented as the mean nuclear-to-cytoplasmic ratio ± the standard deviation. (B) Cells were infected with wt or dIE1 at 3 PFU/cell. Samples were fixed at 48 hpi and stained as described for panel A. STAT3 staining of IE2-positive mitotic cells (left panels) or STAT3 colocalization with IE1 at mitotic chromatin (right panels) is shown. Bars, 10 μm. (C) Cells were infected as described for panel B, and extracts were isolated at 24 hpi. Samples were subjected to immunoprecipitation (IP) using antibodies to IE1 or IE2, and Western blot analysis was completed on lysate and IP samples using the indicated antibodies. (D) Cells were infected as described for panel B, and extracts were isolated at 6 to 72 hpi. Samples were subjected to immunoprecipitation using an antibody to STAT3 or normal rabbit IgG, and Western blot analysis was completed on lysates and IP samples with the indicated antibodies.
STAT3 within the nuclei of TetR-IE1 cells (Fig. 5A). STAT3 relocalization did not occur in control TetR cells (Fig. 5A). By 24 to 72 h poststimulation, greater than 90% of the IE1-positive cells contained STAT3 within the nucleus (Fig. 5B), but these nuclei did not exhibit detectable pSTAT3 (see Fig. S3 in the supplemental material). Furthermore, STAT3 again colocalized with the viral protein and DAPI-stained mitotic chromatin upon induction of IE1 (Fig. 5C). Consistent with previous studies (17), induction of IE1 expression relocalized only a fraction of STAT1 to the nucleus, with delayed kinetics compared to STAT3 (see Fig. S2A and C in the supplemental material), while not apparently altering the subcellular distribution of STAT2 (see Fig. S2B and C). We also evaluated changes in STAT3 phosphorylation upon IE1 expression. Increased expression of IE1 correlated with decreased levels of phosphorylation at Y705, while the total levels of STAT3 remained constant (Fig. 5D). Under these conditions, IE1 was sufficient to suppress the levels of SOCS3 RNA (Fig. 5E). Finally, induction of IE1 suppressed exogenous IL-6/IL6R-stimulated phosphorylation of STAT3 (Fig. 5F; see also Fig. S3), SOCS3 promoter binding by STAT3 (Fig. 5G), and SOCS3 expression (Fig. 5H). These data indicate that expression of IE1 is sufficient to promote the nuclear accumulation of mostly unphosphorylated STAT3, inactive for sequence-specific DNA binding at the SOCS3 promoter, and to alter expression of the STAT3-regulated gene SOCS3.

Disruption of STAT3 relocalization inhibits HCMV DNA replication. The rapid accumulation of unphosphorylated STAT3 in the nucleus during infection suggests that HCMV might utilize STAT3 for viral replication. To test this hypothesis, we evaluated the impact of chemical inhibitors of STAT3 on HCMV infection. The inhibitors included the following: S3i-201, which inhibits STAT3 dimerization and DNA binding (38); curcumin, a natural plant polyphenol which functions, in part, by inhibiting STAT3 DNA binding (39–42); Statistic, which interferes with STAT3 phosphorylation and dimerization (43); WP1066, which blocks upstream JAK2-mediated phosphorylation (44). Initially, we tested whether the compounds influenced HCMV-mediated localization of STAT3. U373 cells were pretreated with DMSO or noncytotoxic concentrations of each compound (Fig. 6A). We infected cells at a multiplicity of 5 IU/cell and evaluated STAT3 accumulation by immunofluorescence microscopy. Compared to DMSO (N/C, 5.30 ± 0.12), both S3i-201 (N/C, 1.26 ± 0.10) and curcumin (N/C, 1.13 ± 0.40) treatments significantly reduced the accumulation of STAT3 in the nuclei of infected cells (Fig. 6B). Statistic treatment resulted in an intermediate phenotype (N/C, 2.64 ± 0.80), while inhibition of JAK-mediated phosphorylation by using WP1066 failed to block the HCMV-mediated change in STAT3 localization (N/C, 5.45 ± 0.90) (Fig. 6B).

Next, we quantified the impact of inhibiting STAT3 on HCMV replication. U373 cells were pretreated with DMSO or compound and infected at 0.25 IU/cell using ADwt virus. We quantified changes in HCMV viral DNA levels by using qPCR. The addition of S3i-201 resulted in a 99.7% reduction in viral DNA levels, curcumin resulted in a 94.0% reduction, Statistic resulted in an 89.5% reduction, and WP1066 had no effect on DNA replication (Fig. 6C). Interestingly, the percent reduction was proportional to the change in the nuclear/cytosolic ratio for STAT3 (Fig. 6B). With S3i-201, we observed the greatest decrease in DNA replication at $\approx 120 \mu M$ (Fig. 7A). The efficacy of S3i-201 inhibition was influenced by the MOI. Although still inhibiting replication, infection at 3 IU/cell resulted in an approximately 71.2% decrease in viral DNA replication (Fig. 7B). We also evaluated the antiviral efficacy of S3i-201 during infection of primary human foreskin fibroblasts and retinal pigmented epithelial cells. Fibroblasts and U373 cells were infected at 0.25 IU/cell with ADwt virus, while epithelial cells were infected using the clinical isolate TB40/E. Chemical inhibi-
FIG 5 IE1 is sufficient to alter STAT3 localization and to inhibit STAT3 phosphorylation, DNA binding, and target gene expression. (A) TetR-IE1 and TetR cells were treated with Dox for 0 to 72 h or 72 h, respectively. Samples were fixed, incubated with antibodies against IE1 (green) and STAT3 (red), and counterstained for DNA using DAPI (blue). Bar, 10 μm. (B) The percentage of positive cell nuclei was determined from 100 randomly selected cells per sample (IE1 -, no IE1 staining above background; IE1 +, weak, mostly punctate IE1 staining; IE1 ++, strong, diffuse IE1 staining; STAT3 -, STAT3 staining mostly cytoplasmic; STAT3 +, STAT3 staining cytoplasmic and nuclear; STAT3 ++, STAT3 staining mostly nuclear). (C) TetR-IE1 and TetR cells were treated with Dox. Samples were fixed at 48 hpi and stained as described for panel A. Representative mitotic cells are shown. Bar, 10 μm. (D) TetR-IE1 cells were treated with Dox for 0 to 72 h, and Western blot analysis was completed using the indicated antibodies. (E) TetR-IE1 and TetR cells were treated with Dox for 0 to 72 h. Relative SOCS3 mRNA levels were determined by qRT-PCR and are presented relative to TUBB expression and TetR at time zero. Data represent two biological and two technical replicates, and values are given as the mean ± standard deviation. *, below detection limit. (F) TetR-IE1 and TetR-IE1 cells were treated with Dox for 72 h and with IL-6 and IL-6Rα or solvent. Western blot analysis was completed using the indicated antibodies. (G) TetR-IE1 and TetR cells were treated with Dox for 72 h and with IL-6 and IL-6Rα or solvent for 30 min. Samples were subjected to ChIP with an antibody to STAT3 or normal rabbit IgG and primers specific for sequences in the SOCS3 promoter or transcribed region. The percentage of output versus input DNA was calculated and is presented as the difference between STAT3 and normal IgG ChIPs. Data represent two biological and two technical replicates, and values are given as the mean ± standard deviation. (H) TetR and TetR-IE1 cells were treated with Dox for 72 h and with IL-6 and IL-6Rα or solvent. Relative SOCS3 mRNA levels were determined by qRT-PCR and are presented relative to TUBB expression and TetR. Data represent three biological and two technical replicates, and values are given as the mean ± standard deviation.
Chemical disruption of STAT3 significantly reduced viral DNA replication at 72 hpi in all of the cell types and viral strains (Fig. 7C). Finally, we determined the impact of STAT3 inhibition on viral titers at 96 hpi from cells treated with either DMSO or S3i-201. We observed that the addition of S3i-201 resulted in an average 2.3-log reduction in viral titers (Fig. 7D). These data suggest that STAT3 nuclear localization is linked to efficient HCMV DNA replication and virus production in multiple cell types.

To provide evidence that the disruption is STAT3 dependent, we knocked down STAT3 expression by transfecting U373 cells with an siRNA targeting STAT3 or with control siRNA. We analyzed changes in STAT3 protein expression by Western blotting and observed a reduction in STAT3 levels with the specific siRNA compared to the control (Fig. 8A). Albeit reduced, we did observe STAT3 within the nucleus in cells transfected with the specific siRNA (Fig. 8B). To evaluate the impact on HCMV viral DNA replication, siRNA-transfected U373 cells were infected at 0.25 IU/cell, and we quantified changes in viral DNA levels by using qPCR. Compared to the control, we observed a 5-fold reduction in viral DNA replication upon reduced levels of STAT3 (Fig. 8C). These data provide additional evidence that STAT3 is necessary for fully efficient viral DNA replication.

Herpesvirus gene expression is temporally regulated, with kinetic classes defined as immediate early (IE), early (E), early-late (E-L), and late (L). Efficient late gene expression is dependent upon DNA replication (1). To identify the steps in replication that require STAT3, we quantified changes in viral gene expression. U373 cells were pretreated with DMSO or S3i-201 and infected using the AD\textsubscript{wt} virus at 0.25 IU/cell. Total RNA was harvested, and viral gene expression was quantified relative to GAPDH RNA. We observed similar levels of expression for the IE and E genes UL123 (IE1) and UL38, respectively, between mock and S3i-201 treatments (Fig. 9A). However, beginning around 24 hpi, the addition of S3i-201 significantly decreased expression of UL122 (IE2), UL83, and UL99. We confirmed these changes by Western blot analysis of whole-cell lysates from HCMV-infected U373 cells (Fig. 9B). In addition to changes in the IE2-86kDa (pUL122) protein, we observed decreased expression of the IE2-
60kDa late isoform following S3i-201 treatment (Fig. 9B). Furthermore, expression levels of two viral proteins with E-L kinetics, pTRS1 and pUL44, were also inhibited (Fig. 9B) beginning at 24 hpi. These data demonstrated that inhibition of STAT3 disrupts viral gene expression beginning around 24 hpi, with the greatest impact seen after 48 hpi for HCMV IE2, E-L, and L genes.

The accumulation levels of E-L and L transcripts as well as of UL122 is dependent on viral DNA synthesis (45–47). Furthermore, HCMV IE2, pUL44, and pTRS1 have been demonstrated to contribute to genome replication (33, 48–53). To test the timing of STAT3’s contribution to HCMV replication, we treated U373 cells with S3i-201 at different times during infection. Cells were infected at 0.25 IU/cell with AD\textsubscript{wt} virus and treated with S3i-201 at 2 hpi or at 48 hpi for 24 h. We isolated DNA at 72 hpi and quantified viral genomes by using qPCR. Consistent with previous data, S3i-201 treatment early during infection resulted in a significant decrease in viral DNA levels (Fig. 9C). Conversely, treatment at 48 hpi resulted in no significant difference in viral DNA compared to control infection (Fig. 9C). These data suggest that HCMV relocalizes STAT3 early to regulate early and late events during infection, including efficient viral DNA replication.

### DISCUSSION

We have determined that HCMV infection promotes nuclear accumulation of STAT3 that is predominantly or entirely unphosphorylated at Y705. In the canonical pathway from uninfected cells, STAT3 is activated by a variety of different stimuli, including cytokines and growth factors, resulting in phosphorylation of Y705 (pSTAT3) and accumulation in the nucleus (18, 22). Unlike HCMV, herpesviruses that infect cells of lymphoid origin, including Epstein-Barr virus (EBV) (54, 55), Kaposi’s sarcoma-associated herpesvirus (KSHV) (56), herpesvirus saimiri (HVS) (57), and varicella-zoster virus (VZV) (58) exploit the survival and oncogenic effects of pSTAT3. Beyond herpesviruses, several onco- genic viruses utilize pSTAT3, while other viruses employ mechanisms to inhibit STAT3 signaling (59, 60). Within our studies, we observed that disrupting the nuclear accumulation of STAT3 or STAT3 expression inhibited HCMV infection at the stage of viral DNA replication. These studies are the first example of a virus that inhibits phosphorylation of STAT3 at Y705 yet still requires its activities for viral replication.

We found that the HCMV IE1 protein is necessary to relocalize STAT3 to the nucleus at early times during infection, and the viral

**FIG 7** S3i-201 inhibits HCMV replication in multiple cell types. (A) Cells were pretreated with increasing concentrations of S3i-201. After 24 h, cells were infected at 0.25 IU/cell with AD\textsubscript{wt}. Viral genomes were quantified at 72 hpi by qPCR and normalized to cellular DNA. Data represent two biological replicates, and values are given as the mean ± SEM. *P < 0.05. (B) U373 cells were pretreated with 125 μM S3i-201. After 24 h, cells were infected at 3 IU/cell with AD\textsubscript{wt}. Viral genomes were quantified as described above. Data represent two biological replicates, and values are given as the mean ± SEM. *P < 0.05. (C) Different cell types were pretreated with 125 μM S3i-201. U373 and HFF cells were infected at 0.25 IU/cell with AD\textsubscript{wt}, while ARPE19 cells were infected at 0.25 IU/cell with TB40/E. Viral genomes were quantified as described above. Data represent two biological replicates, and values are given as the mean ± SEM. *P < 0.05. (D) U373 cells were pretreated with drug as described above. At 24 h, cells were infected at 0.25 IU/cell with AD\textsubscript{wt}. Viral titers were determined from culture supernatants obtained at 96 hpi. Data represent two biological replicates, and values are given as the mean ± SEM. *P < 0.05.

**FIG 8** siRNA targeting STAT3 attenuates viral DNA replication. (A) Serum-starved U373 cells were transfected with control siRNA or siRNA targeting STAT3. After 24 h, Western blot analysis was completed using the indicated antibodies. (B) Cells were transfected as described above. After 24 h, cells were processed for immunofluorescence analysis using anti-STAT3 (green) and DAPI (blue). The mean fluorescent intensities of STAT3 within the nucleus and cytoplasm were obtained from an average of 20 to 30 cells and from at least two replicate experiments. The data are presented as the nuclear-to-cytoplasmic ratio ± SEM. (C) Cells were transfected as described above. After 24 h, cells were infected with AD\textsubscript{wt} virus at 0.25 IU/cell. Viral genomes were quantified at 72 hpi by qPCR and normalized to cellular DNA. Data represent two biological replicates, and values are given as the mean ± SEM. *P < 0.05.
protein is also sufficient to induce nuclear STAT3 accumulation. The effects of IE1 on the subcellular distribution of STAT3 seem to be independent of phosphorylation at Y705 or cytokine stimulation. IE1 (also known as IE1-72kDa, or IE72) is a nuclear regulatory phosphoprotein expressed from the HCMV genome at the start of infection. IE1 has long been known to attach to human chromosomes (12), but it is not considered to bind directly to DNA (61). We observed that IE1 expression promoted the association of STAT3 with mitotic chromatin, yet disrupted STAT3 binding to the SOCS3 promoter. Unphosphorylated STAT3 has been demonstrated to shuttle between the nucleus and the cytosol (27–30), and we speculate that STAT3 nuclear export may be prevented by interactions with IE1 at cellular chromatin and/or other nuclear compartments.

One functional consequence of IE1-mediated nuclear localization of STAT3 is the suppression of IL-6-induced SOCS3 gene expression. Previous studies demonstrated that upregulation of IL-6 by HCMV pUS28 resulted in pSTAT3 at Y705 (62). Consistent with these findings and other studies (62, 63), we observed a transient increase in IL-6 expression that occurred only at 2 hpi and was not affected by S3i-201 (data not shown). Furthermore, we did detect increased pSTAT3 (Y705) by Western blotting when we infected most but not all of the cells in culture. Under these conditions, phosphorylation of STAT3 occurred mostly in the uninfected cells within this population. Finally, Le et al. (64) have demonstrated that HCMV infection can disrupt IFN-γ-stimulated STAT3 phosphorylation starting at 24 hpi. Our studies indicate that nuclear STAT3 is predominantly unphosphorylated at Y705 in cells infected by either lab-adapted or clinical strains of HCMV.

Our data indicate that HCMV primarily utilizes unphosphorylated STAT3 to promote, either directly or indirectly, the initiation of HCMV DNA replication. Consistent with this idea, the addition of S3i-201 after 48 hpi had no effect on DNA replication. We found that inhibition of STAT3 severely attenuated viral DNA replication, the expression of numerous viral genes, and consequently, the production of infectious viral progeny. At 24 hpi, we observed similar levels of expression for HCMV IE1, IE2, and pUL38 following STAT3 inhibition. However, we detected a sub-

FIG 9 STAT3 is necessary for efficient HCMV gene expression and genome replication. (A) U373 cells were pretreated with DMSO or 125 μM S3i-201. After 24 h, cells were infected at 0.25 IU/cell with ADwt. Levels of the indicated RNAs were quantified by qRT-PCR and are presented relative to GAPDH. Data represent two biological replicate experiments, and values are given as the mean ± SEM. *, P < 0.05. (B) U373 cells were pretreated with drug as described above, and after 24 h, viral genomes were quantified by qPCR and normalized to cellular DNA levels. Data represent two biological replicates, and values are given as the mean ± SEM. *, P < 0.05.
stallent decrease in expression of the viral polymerase subunit pUL44. The decrease in pUL44 levels may be attributed to decreased pTRSI, since pTRSI functions in cooperation with IE1 and IE2 to stimulate UL44 expression (52, 65). After 24 hpi, the increase in IE2-86kDa, IE2-60kDa, pTRSI, and pUL99 levels failed to occur upon inhibiting STAT3. These changes have been shown to be dependent upon viral DNA replication (66–69). A similar phenotype occurred upon deletion of the HCMV protein pUL21a which, along with pUL97 kinase, negatively regulates the anaphase-promoting complex (45, 67, 70). Disruption of pUL21a resulted in reduced DNA replication and late expression of a subset of proteins, including IE2 and pUL99 (67).

We demonstrated that chemical antagonists of STAT3 significantly inhibited HCMV infection. Similar observations have been made in experiments involving inhibitors of STAT3 and VZV infection (58). Numerous malignancies are characterized by elevated STAT3 expression and activity (71). As a result, STAT3 inactivated STAT3 to promote an environment that supports efficient viral replication (72–74), which also inhibit HCMV replication trials as anticancer agents (71). Several FDA-approved compounds have been shown to inhibit STAT3 activity, such as Celebrex and Sorafenib (72–74), which also inhibit HCMV replication in vitro (75, 76). Overall, our studies indicate that HCMV manipulates STAT3 to promote an environment that supports efficient viral DNA replication, and the findings implicate STAT3 as a possible target for anti-HCMV antiviral research.

ACKNOWLEDGMENTS

We thank T. Shenk for the HCMV antibodies. We thank Theresa Knoblach, Benedikt Grandel, Nathalie Czech, and Thomas Harwardt for experimental contributions and Sandra Meinell for technical assistance. We also thank M. Hakki and the members of the Terhune and Nevels labs for their insights and helpful discussions.
