Cover photograph (Copyright © 2015, American Society for Microbiology. All Rights Reserved.): Contact between an HIV-1-infected T cell and an uninfected T cell results in the formation of a multimolecular structure, termed the virological synapse (VS), which promotes efficient cell-cell spread of the virus. The immunofluorescence image shows a volume rendering from different angles of a VS in which the major HIV-1 structural protein (Gag, green) and mitochondria (red) are seen polarized within the infected T cell toward the site of contact with an uninfected T cell (blue). (See related article on p. 14.)
